In order to examine the ability of multi-multi-walled carbon nanotube for CO$_2$ separation from flue gas, uptakes of CO$_2$ and N$_2$ were measured at temperatures of 288 K, 298 K and 308 K over the pressure range 1 to 40 bar using volumetric method. The experimental data was fitted by the Langmuir and Freundlich model isotherms. The same shape of isotherms introduced a common mechanism of adsorption but the amount of CO$_2$ adsorbed on multi-multi-walled carbon nanotube was 2.5 times higher than N$_2$ adsorption which indicated the possibility of CO$_2$ removal from flue gases using adsorption process with multi-multi-walled carbon nanotube as the adsorbent. Isosteric heat of adsorption was evaluated from a set of isotherms based on the Clausius–Clapeyron equation.

1. Introduction

Human activities, such as the combustion of fossil fuels have increased CO$_2$ concentrations in the atmosphere. CO$_2$ is one of the major greenhouse gases responsible for global warming [1]. Several technologies have been proposed to capture CO$_2$ including chemical absorption, cryogenic separation, physical adsorption, and membrane separation. Among these chemical absorption with aqueous solution is the most famous one [2]. But disadvantages of this method cause that physical adsorption plays an important role in the adsorption of CO$_2$ [3, 4]. Since the discovery of carbon nanotube (CNT) by Iijima in 1991, because of their unique properties such as uniform porosity, high effective surface area and low mass density, many researches were done on these new kinds of porous adsorbents [5]. In this study the potential of multi-multi-walled carbon nanotube (MWCNT) as an adsorbent for CO$_2$ removal from flue gas (mixture of CO$_2$ and N$_2$) was studied. Also experimental results of CO$_2$ and N$_2$ adsorption by MWCNT at equilibrium state were described by the Langmuir and Freundlich isotherms. Isosteric heat of adsorption was evaluated considering the Clausius–Clapeyron equation.

2. Apparatus

The amounts of gas adsorbed on the MWCNT were measured by using a volumetric method (Fig. 1). The apparatus used consisted of two pressure and adsorption cells that were put in a water bath to maintain the temperature constant. Before each test, the adsorbent was degassed at 473 K for 24 h and the system was evacuated by vacuum pump to 0.1 mbar. Prior the MWCNT was introduced into the adsorption cell, the setup was leak tested using air for 24 h to ensure that there was no pressure drop at the different operating pressures. Also the He gas was used to determine the dead volume. The amounts of gases adsorption were obtained by Soave–Redlich–Kwong (SRK) equation of state and the material balance before and after each test.
The Langmuir isotherm is given in the following equation:

$$q_e = q_m \frac{K_l P}{1 + K_l P}.$$  \hfill (1)

The Freundlich isotherm is given by

$$q_e = K_F P^\frac{1}{n}.$$  \hfill (2)

Figure 3a shows the comparison of experimental adsorption data to predicted values by the Langmuir and Freundlich isotherm models. By inspecting the $R^2$-squared values (regression correlation coefficients) (Table), parameters obtained demonstrated that both models give good fit with experimental data. The maximum gas capacity ($q_m$) for adsorption and $K_L$ values decreased with increasing temperature. These represent that the affinity between CO$_2$ and N$_2$ MW CNT had an inverse relationship with temperature and represent an exothermic reaction. The $K_F$ value of the gas adsorbed by the MWCNT decreased when the temperature increased.

These results suggested that the adsorption of the both gases on these sorbent is more favorable at low temperature. The trend of changes for CO$_2$ and N$_2$ adsorption on MWCNT were the same which approve similarity in adsorption mechanism for these gases. Heat of adsorption reflects the enthalpy variation before and after adsorption which is defined by the Clausius-Clapeyron equation:

$$\Delta H_{st} = R \frac{\ln p}{d(1/T)} \bigg|_{q_e}.$$  \hfill (3)

The plot of $\ln p$ versus $1/T$ gives the isosteric heat of adsorption. A rule of thumb in adsorption is that heat of adsorption of 80 kJ/mol or more confirms chemisorption and smaller values is representative of physisorption [6].

The obtained amounts of $\Delta H_{st}$ indicated that the process of adsorption was physisorption. By increasing $q_e$, $\Delta H_{st}$ decreased, because in lower pressure gas molecules can come into direct contact with the MWCNT. This causes a stronger interaction between gases and MWCNT. The occupation of pores at higher gas pressure caused a weak interaction between gases and MWCNT. Hence, the adsorption enthalpy decreased. A comparison between $\Delta H_{st}$ (Fig. 3b) revealed that the heat of adsorption of CO$_2$ was higher compared with N$_2$ at all surface coverages. This showed that CO$_2$ was adsorbed more strongly on MWCNT. Since the molecular mass of CO$_2$ is higher than N$_2$, this caused increase of Van der Waals forces between CO$_2$ molecules and adsorbent.

4. Conclusion

The equilibrium uptake of CO$_2$ and N$_2$ by multi-multi-walled carbon nanotube adsorbent was measured. The experimental isotherm data confirmed that the affinity between CO$_2$ and N$_2$ on MWCNT had an inverse relationship with temperature. In conclusion, the general results obtained indicated that MWCNTs is a promising adsorbent for CO$_2$ removal from flue gas (mixture of CO$_2$ and N$_2$).
