Image Force Effect on the Separation of Partial Dislocations in Bicrystals of Hexagonal Structure Zn–Tl and Zn–Be

A. Ayadi and O. Khalfallah

Laboratory of Microstructures and Defects in Materials, Mentouri University, Constantine, Algeria

We study the elastic interaction between a pair of partial dislocations, resulting from the dissociation of a perfect dislocation, and a bimetallic interface. The forces that act on two partials dislocations are the forces due to elastic interaction between the partial and image forces due to interactions of partial dislocations with interface. We are interested in the effect of image force on width of the stacking fault ribbon between two Schottky partials. We show that the separation of two partials dislocations is modified compared to that in the single crystal. It depends on the ratio of shear modulus and the distance between the interface and the dislocation.

1. Introduction

The perfect dislocations dissociate into partial dislocations with creating a stacking fault. The differences in mechanical behavior between the materials come from the ease or difficulty for dislocations to dissociate. When the dislocations are dissociated, they lose their mobility and the material presents high work hardening ability. We can thus characterize metals and alloys due to their stacking fault energy which is measured from the distance of separation of partial dislocations. This energy was derived by Read [1] for isotropic medium and by Chou and Eshelby [2] for an anisotropic crystal, and it depends on the crystal structure. This energy was derived by Read [1] for isotropic medium and by Chou and Eshelby [2] for an anisotropic crystal, and it depends on the crystal structure. This energy is denoted $\gamma$, and is inversely proportional to the distance between the partials. Studies of elastic interactions between dislocations and interface made by Priester and Khalballah [3-5] showed that the image force in elastically anisotropic materials plays an important role in the dislocation movement vis-à-vis the interface. As well analysis of the image force exerted on a dislocation near a bimetallic interface was taken in detail by Dundurs and Sendreckyj [6], Lin and Lee [7] and Lin [8]. For this purpose we investigate the behavior of dissociated dislocations near the interface.

2. Configuration of dislocations and studied materials

An edge perfect dislocation, the Burgers vector $b$, located in the basal plane (0001) of a material with hexagonal structure, can dissociate into a pair of Schottky partial dislocations with the Burgers vectors $b_1$ and $b_2$ according to the following:

$$\frac{a}{3}[1120] \rightarrow \frac{a}{3}[1010] + \frac{a}{3}[0110].$$

The leading partial dislocation is located at distance $d$ of the interface and the queue partial dislocation is at distance $(d+l)$ from the interface, Fig. 1. They are parallel to the interface and are in elastic interaction with it. The interface is defined by its plane which is the basal plane for the two crystals and its disorientation which is null.

Fig. 1. Schematic of two partial dislocations near the interface Zn-X. $l$ — width of separation between two Schottky partials, $d$ — distance between the interface and the leading partial dislocation.

The bicrystal consists of two metals of hexagonal structure, the first is zinc and the second is beryllium or tellurium. The two metals are selected to obtain ratios of shear modulus $\mu_2/\mu_1 > 1$ for Zn–Be bicrystal and $\mu_2/\mu_1 < 1$ for Zn–Tl where $\mu_{Zn} = 46.6$ GPa, $\mu_{Be} = 149.9$ GPa and $\mu_{Tl} = 6.2$ GPa [9, 10]. The two partial dislocations are located in zinc crystal.

3. Results and discussion

Determining the separation distance between the two partials, in interaction with the interface, requires the calculation of forces acting on them: the elastic interaction force, $F_{el}$, by the Peach–Koehler law and the image force, $F_i$, by the theorem of Barnett and Lothe [9].

- The force due to elastic interaction, $F_{el}$, between the partials is calculated in a single crystal of zinc. It controls the separation distance, $l$, of the two partials:

$$F_{el} = \mu_{Zn}b^2/2\pi l.$$  

- The image forces, $F_{i1}$ and $F_{i2}$, exerted on each partial. They are controlled by their distances from the interface: $d$ for the leading partial and $(d+l)$ for the queue
Image Force Effect on the Separation of Partial Dislocations ... 303

3.1. Image Force Effect on the Separation of Partial Dislocations

Partial

$$F_{1} = -\frac{E_{1}}{d} \frac{d_{1}}{d_{1}} - E_{1} = \frac{\Delta E}{d}, \quad (3)$$

$$F_{2} = -\frac{E_{2}}{d} \frac{d_{2}}{d_{2}} - E_{2} = \frac{\Delta E}{d + l}, \quad (4)$$

Where $\Delta E$ is the elastic energy of dislocation-interface interaction. $F_{1}$ (Eq. (3)) is the image force corresponding to the leading partial dislocation is located at distance $d$. $F_{2}$ (Eq. (4)) is the image force corresponding to the queue partial dislocation is at distance $(d + l)$ from the interface.

The difference between the two partials is exerted on each of the two partial $\Delta F = \frac{\Delta E}{d}$.

The new partial separation $l'$ under the effect of the image force is obtained by the relation:

$$F_{1} = (\mu_{2}b_{2}^{2}/2\pi l) + \Delta F = \mu_{2}b_{2}^{2}/(2\pi l'). \quad (5)$$

We take the force of interaction misfit dislocation-partial dislocation as a constant.

The elastic interaction energies, $\Delta E$, of the Shockley partials with interface for the bicrystals Zn-Be and Zn-Tl are shown in Table.

4. Conclusion

The effect of image force plays an important role on interaction of partial dislocations with bimetallic interface in case of bicrystal of hexagonal structure. The image force modifies the equilibrium separation of partials compared to that in a single crystal. Separation of the two partial dislocations depends on the ratio of shear modulus of the two materials which constitute the bicrystal. The stacking fault ribbon issued from the dissociation of a perfect dislocation is expanded under effect of image force for a dislocation close to second harder crystal. The image effect decreases stacking fault energy of first crystal which contains the dislocation. The same ribbon is narrowed when the second crystal is softer than the first, then the stacking fault energy is increased under the influence of the image force.
