The compound SbNbO\textsubscript{4} that is formed in a ternary system of Nb-Sb-O has been obtained for the first time by high-energy ball milling of the equimolar mixture of oxides Sb\textsubscript{2}O\textsubscript{3}/Nb\textsubscript{2}O\textsubscript{5} in argon atmosphere. This compound was characterised by X-ray diffraction, differential thermal analysis-thermal gravimetry, infrared, and scanning electron microscopy methods and its properties were compared with those of SbNbO\textsubscript{4} also obtained as a result of high-temperature reaction between the same oxides and also in argon atmosphere. As shown by differential thermal analysis results, irrespective of the method of synthesis, SbNbO\textsubscript{4} is stable in argon atmosphere up to \( \approx 1125^\circ \text{C} \) and in air up to \( \approx 800^\circ \text{C} \). The compound can be applied as a photocatalyst in the reaction of producing hydrogen from water.

1. Introduction

As follows from the information on the binary systems of niobium and antimony oxides, describable by the formula Nb-Sb-O, there are no phases formed in this system in which both antimony and niobium would be at the highest oxidation state, +5. The formation of the compounds SbNbO\textsubscript{4}, Sb\textsubscript{2}Nb\textsubscript{3}O\textsubscript{13} and Sb\textsubscript{0.67}Nb\textsubscript{2}O\textsubscript{6}, in which antimony and/or niobium are at lower oxidation states has been reported and the formation of a solid solution SbNbO\textsubscript{4} described by the formula Sb\textsubscript{a}Sb\textsubscript{b}Nb\textsubscript{1-x}O\textsubscript{4}, where 0.0 < x < 1.0 has been signalled \([1-13]\). With regard to its application potential, the most attention has been paid to SbNbO\textsubscript{4} in which antimony is at +3 and niobium at +5 oxidation state. This compound was for the first time obtained in the 1960s by Roth and Waring \([2]\) as a result of heating of oxides Sb\textsubscript{2}O\textsubscript{3} and Nb\textsubscript{2}O\textsubscript{5} mixture sealed in platinum ampoules, at temperatures from the range 995–1103\(^\circ\text{C}\) for many hours. According to the authors of \([9]\) this solid compound can be obtained also by the solid state reaction when a mixture Sb\textsubscript{2}O\textsubscript{3}/Nb\textsubscript{2}O\textsubscript{5} is heated in argon atmosphere at 900\(^\circ\text{C}\) for 2 h. Single crystals of this compound have been also obtained by the hydrothermal method at temperatures from the range 400–450\(^\circ\text{C}\) under a pressure from the range 650–670 atm \([3-7]\). The structure of the compound SbNbO\textsubscript{4} has been determined \([6-9]\) and its physicochemical properties (including electric, magnetic, optical and photocatalytic ones) have been established \([4-6, 9]\). According to the updated results \([9]\) it crystallises in the orthorhombic system \((a = 5.568 \text{Å}, b = 11.811 \text{Å}, c = 4.938 \text{Å})\) and has a lamellar structure. Nb ions are octahedrally coordinated with the oxygen atoms to build NbO\textsubscript{6} octahedra. They are connected by sharing four corners, and Sb\textsuperscript{3+} ions are located in between these octahedral layers. The Sb\textsuperscript{3+} ions are surrounded by six oxygen atoms, forming strongly distorted SbO\textsubscript{6} \([9]\). It is known that SbNbO\textsubscript{4} is a ferroelectric in the temperature range from \(\approx 400\) to \(\approx 600^\circ\text{C}\) \([5]\) and that it shows photocatalytic activities for H\textsubscript{2} evolution from water splitting \([9]\). For this reason it has been a subject of great interest.

Taking into regard the current state of knowledge on the properties of SbNbO\textsubscript{4}, and in particular its possible use as a ferroelectric photocatalyst \([9]\), the main aim of our study was to establish if this compound can be obtained by any other method than the hitherto used high-energy ball milling. As follows from the review on mechanochemistry \([14]\) the methods based on this principle not only satisfy the criteria of green chemistry but they also permit a fast and easy synthesis of different composites, including those of micro- and nanomaterials of desired electric, magnetic and catalytic properties \([15, 16]\). This study was also undertaken to compare the fundamental physicochemical properties of SbNbO\textsubscript{4} obtained from the equimolar mixture of Sb\textsubscript{2}O\textsubscript{3}/Nb\textsubscript{2}O\textsubscript{5} by the mechanochemical method and by the high-temperature solid state reaction.

2. Experimental

2.1. Materials synthesis, equipment and procedures

The polycrystalline samples of SbNbO\textsubscript{4} were prepared by using two different methods, namely:
1. Mechatrochemical synthesis (MChS) using laboratory planetary ball mill Pulverisette-6 (Fritsch GmbH, Germany) with vessel and balls of zirconia, rp = 500, BPR = 1 : 20, time = 5 h and under argon atmosphere.

2. High-temperature synthesis (HTS) in a horizontal tube furnace (CTF 12/65/550, Carbolite, UK) in the atmosphere of deoxidized argon (99.996%) flowing at the rate 5 dm$^3$/h.

For the mechatrochemical synthesis appropriate amounts of T-Nb$_2$O$_5$ and Sb$_2$O$_3$ (both of 99.99% purity, Aldrich, USA) were mixed in a stoichiometric molar ratio to SbNbO$_4$ and then milled at the time of 1.5, 3.0, and 5.0 h.

For the high-temperature synthesis the same reagents were mixed and pressed into pellet discs with 10 mm in diameter. These discs were heated in the atmosphere of argon at 600, 650, 700 in 24 h stages respectively. Both methods are described, *inter alia*, in the works [15–18].

2.2. Characterization of as-synthesized materials

The as-synthesized materials were analysed via a powder X-ray diffraction with a Cu $K\alpha$ source on an X'Pert and Empyrean Philips instrument, for $2\theta = 10^\circ-45^\circ$ with a step size of 0.02$^\circ$. The identification of the material was made according to a JCPDS Table: 30-873, 5-534, 11-689, 86-2243.

The microstructure and morphology of the obtained polycrystals were examined with the use of an electron scanning microscope — SEM (JSM-6100, JEOL, Japan).

IR spectroscopy analysis was made by the use of Spectrometer (Specord M80, Carl Zeiss) (tablets with KBr in molar ratio 1:300).

The obtained samples were also subjected to examination by the differential thermal analysis—thermal gravimetric (DTA-TG) method with the use of a SDT 2960 apparatus, made by the TA Instruments Company. The measurements were taken in argon atmosphere, within the temperature range 20-1300°C, at the heating rate of 10 deg/min. The tests were conducted in corundum crucibles. The mass of the samples was $\approx$ 20 mg.

3. Results and discussion

As follows from analysis of phase composition (XRD) of the samples obtained after subsequent stages of mechatrochemical synthesis from the equimolar mixture of oxides $\alpha$, $\beta$-Sb$_2$O$_5$/T-Nb$_2$O$_5$ in argon (the commercial Sb$_2$O$_3$ is a mixture of two polymorphic varieties $\alpha$ and $\beta$), the monophase product containing only SbNbO$_4$ was obtained after 5 h of high-energy ball milling. A comparison of the fragments of diffractograms obtained for the samples synthesised (Fig. 1), significant amount of SbNbO$_4$ is formed in the reaction mixture already after 1.5 h of milling.

It has been also established that as a result high-temperature heating of the same mixture of the oxides in a tube furnace under flowing argon, the pure compound SbNbO$_4$ is obtained after three 24 h stages of the reactants heating at 600, 650, and 700°C. A fragment of XRD diffractogram of the equimolar mixture of Sb$_2$O$_3$/Nb$_2$O$_5$ and the product obtained after its heating at 700°C (24 h) is shown in Fig. 2.

![Fig. 1. Fragments of XRD diffractograms of the equimolar initial mixture of Sb$_2$O$_3$/Nb$_2$O$_5$ and the mixture after high-energy ball milling for 1.5, 3.0, and 5.0 h.](image1.png)

![Fig. 2. Fragments of XRD diffractograms of (1) the equimolar mixture Sb$_2$O$_3$/Nb$_2$O$_5$ and (2) the compound SbNbO$_4$ obtained from this mixture as a result of high-temperature synthesis.](image2.png)

Analysis of XRD diffractograms of the samples after the first (1.5 h) and second (3 h) stage of milling and after the first (600°C–24 h) and second (650°C–24 h) stage of heating permitted assigning their diffraction lines mainly to the set characterising the compounds SbNbO$_4$ and T-Nb$_2$O$_5$, with SbNbO$_4$ the dominant phase. The samples should also contain the unreacted Sb$_2$O$_3$ which was not identified because of very low relative intensity of the XRD lines characterising this oxide in the diffractograms of the mixtures containing SbNbO$_4$ and T-Nb$_2$O$_5$ (see Fig. 1).

The phase composition of all samples studied containing SbNbO$_4$ proved that, irrespective of the method of synthesis, antimony(III) oxide reacts with niobium(V) oxide according to the equation

$$\text{Sb}_2\text{O}_3 + \text{Nb}_2\text{O}_5 \rightarrow \text{SbNbO}_4 + \text{Sb}_2\text{O}_3$$
\[
\text{Sb}_2\text{O}_3(s) + \text{Nb}_2\text{O}_5(s) \rightarrow 2\text{SbNbO}_4(s). \quad (1)
\]

In order to establish the thermal stability of \(\text{SbNbO}_4\), the monophase samples (HEM and HTS) were subjected to DTA-TG studies in argon and in air atmosphere.

The DTA curves of \(\text{SbNbO}_4\) obtained as a result of mechanochemical synthesis (Fig. 3) or a high-temperature reaction (Fig. 4) in argon atmosphere on heating up to \(1300^\circ C\) show one endothermic effect starting at \(1125\pm10^\circ C\).

\[
\text{SbNbO}_4(s) \leftrightarrow \text{H} - \text{Nb}_2\text{O}_5(s) + \text{liquid}. \quad (2)
\]

A solid product of \(\text{SbNbO}_4\) melting in anaerobic atmosphere is thus \(\text{H-Nb}_2\text{O}_5\).

The DTA curve recorded for \(\text{SbNbO}_4\) in air atmosphere, irrespective of the method of synthesis, revealed almost the same effects, see Fig. 5. The first broadened and poorly resolved exothermic effect starts at \(\approx 780^\circ C\), while the second endothermic one starting at \(1040^\circ C\) has a clearly marked inflection point at \(1060^\circ C\).

\[
\text{Fig. 3. The DTA curve of SbNbO}_4\text{in argon atmosphere (MChS).}
\]

\[
\text{Fig. 4. The DTA curve of SbNbO}_4\text{in argon atmosphere (HTS).}
\]

\[
\text{Fig. 5. The DTA curve of SbNbO}_4\text{in air atmosphere.}
\]

The XRD phase analysis of \(\text{SbNbO}_4\) heated in air at \(800^\circ C\) for 2 h revealed the presence of \(\alpha-\text{Sb}_2\text{O}_4\) and \(\text{T-Nb}_2\text{O}_5\). This result indicated that compound \(\text{SbNbO}_4\) is stable in air up to about \(800^\circ C\), then at higher temperatures it undergoes decomposition to the initial oxides, which is accompanied by oxidation of \(\text{Sb}_2\text{O}_3\) to \(\alpha-\text{Sb}_2\text{O}_4\). Additional heating of the products of \(\text{SbNbO}_4\) decomposition in air at \(800^\circ C\) for 48 h led to the formation of solid solutions \(\text{SbSb}_{1-x}\text{Nb}_x\text{O}_4\) and \(\text{Nb}_{2-x}\text{Sb}_x\text{O}_5\).

\[
\text{Fig. 6. SEM images of SbNbO}_4\text{synthesised by (a) high temperature and (b) mechanochemical method.}
\]
At the next stage of the study, the compound SbNbO$_4$ obtained by the two above-described methods was subjected to scanning electron microscopy (SEM). Figure 6a and b reveals differences in the morphology of SbNbO$_4$ crystals obtained by the high-temperature reaction in solid phase (6a) and by mechanochemical synthesis (6b). The compound SbNbO$_4$ obtained by the mechanochemical synthesis has crystals of irregular shapes and inhomogeneous distribution of sizes. Unexpectedly, the largest crystals of SbNbO$_4$ of poorly developed walls were those obtained by high-energy ball milling. Their size varied from $\approx 5 \mu m$ to 0.1 $\mu m$ (100 nm), while the size of crystals of this compound obtained by the high-temperature synthesis varied from 0.15 to 1 $\mu m$.

Taking into account the SEM images (Fig. 6b) and analysis of XRD line widths (Fig. 1 - 5 h MChS) obtained for SbNbO$_4$ synthesised by mechanochemical method, it cannot be excluded that this product contains small amount of amorphous compound besides the crystal form of the compound.

It is worth noting that the resulting SbNbO$_4$ by mechanochemical method had bright orange color when prepared by high temperature was white.

SbNbO$_4$ synthesised by the two methods described above, samples HEM and HTS, have been subjected to IR study. The spectra of the two samples were almost identical. The only difference was that the absorption bands in the IR spectrum of the compound synthesised by the high-temperature treatment were slightly better developed (Fig. 7).

![IR spectrum of SbNbO$_4$ obtained by high-temperature reaction.](image)

The IR spectrum of SbNbO$_4$ shows the absorption bands of the maxima at 720, 636, 616, 468, 424, 404 and 364 cm$^{-1}$. On the basis of literature, the bands with the maxima at 720, 636, 616 and 468 cm$^{-1}$, can be with a high probability assigned to the stretching vibrations ($\nu$) of M–O bonds in the NbO$_6$ octahedrons and in strongly deformed SbO$_6$ octahedrons [19–23]. The bands peaking at 720 and 468 cm$^{-1}$ are assigned to the stretching vibrations of Nb–O bond with the oxygen atom joining two NbO$_6$ octahedrons via a shared vortex. The bands peaking at 324 and 310 cm$^{-1}$ correspond to the deformation vibrations ($\delta$) O–M–O in NbO$_6$ and SbO$_6$ polyhedrons sharing edges and vortices [21–23]. This quantitative analysis of the IR spectrum of SbNbO$_4$ is in good agreement with literature data [7–9] implying that the structure of this compound contains joined NbO$_6$ octahedrons and strongly deformed SbO$_6$ octahedrons.

4. Conclusions

1. The compound SbNbO$_4$ can be obtained from equimolar mixture of Sb$_2$O$_3$/Nb$_2$O$_5$ as a result of solid state reaction in argon atmosphere not only by the high-temperature treatment but also by a much shorter and easier process of high-energy ball milling.

2. Unexpectedly, the mean size of SbNbO$_4$ crystals obtained by the mechanochemical method is much greater than that of the crystals obtained by high-temperature treatment.

3. Irrespective of the method of synthesis, SbNbO$_4$ is stable in argon atmosphere up to $\approx 1125^\circ$C, above which it undergoes incongruent melting with development of solid state II-Nb$_2$O$_5$, while in air atmosphere at $\approx 800^\circ$C it undergoes decomposition to Sb$_2$O$_3$ and Nb$_2$O$_5$ accompanied by oxidation of Sb$_2$O$_3$ to $\alpha$-Sb$_2$O$_4$.

4. IR spectrum confirmed that the compound obtained by the two methods is built of NbO$_6$ octahedrons and strongly deformed SbO$_6$ octahedrons.
